The mean equation of an univariate time series  $x_t$  can be described by the process

$$x_t = E(x_t | \mathcal{F}_{t-1}) + \varepsilon_t, \quad (1)$$

where  $E(\cdot | \cdot)$  denotes the conditional expectation operator,  $\mathcal{F}_{t-1}$  the information set at time  $t - 1$ , and  $\varepsilon_t$  the innovations of the time series.

The ARMA( $m,n$ ) process of autoregressive order  $m$  and moving average order  $n$  can be described as

$$x_t = \mu + \sum_{i=1}^m a_i x_{t-i} + \sum_{j=1}^n b_j \varepsilon_{t-j} + \varepsilon_t, \quad (2)$$

with mean  $\mu$ , autoregressive coefficients  $a_i$  and moving average coefficients  $b_j$ .

# GARCH variance equation

model and the  
SP500 benchmark

The mean equation does not take into account heteroskedastic effects typically observed in financial time series. Engle [1982] introduced the *Autoregressive Conditional Heteroskedastic* model, named ARCH, later generalised by Bollerslev [1986], named GARCH.

$$\begin{aligned}\varepsilon_t &= Z_t \sigma_t, \\ Z_t &\sim \mathcal{D}_\vartheta(0, 1), \\ \sigma_t^2 &= \omega + \sum_{i=1}^p \alpha_i \varepsilon_{t-i}^2 + \sum_{j=1}^q \beta_j \sigma_{t-j}^2, \end{aligned} \quad (3)$$

# APARCH variance equation

GARCH(1,1) model  
and the DEMGBP  
benchmark

MA(1)-APARCH(1,1)  
model and the  
SP500 benchmark

Ding [1993] introduced the APARCH(p,q) variance that can be expressed as

$$\varepsilon_t = Z_t \sigma_t,$$

$$Z_t \sim \mathcal{D}_\vartheta(0, 1),$$

$$\sigma_t^\delta = \omega + \sum_{i=1}^p \alpha_i (|\varepsilon_{t-i}| - \gamma_i \varepsilon_{t-i})^\delta + \sum_{j=1}^q \beta_j \sigma_{t-j}^\delta, \quad (4)$$

where  $\delta > 0$  and  $-1 < \gamma_i < 1$ .

This model adds the flexibility of a varying exponent with an asymmetry coefficient  $\gamma_i$  to take the leverage effect into account and the varying power  $\delta$  to consider the Taylor effect.

- `garchSpec()` - specifies a GARCH model.
- `garchSim()` - simulates an artificial GARCH time series.
- `garchFit()` - fits the parameters to the model using the maximum log-likelihood estimator.
- `print`, `plot`, `summary`, - are S3 methods for an object returned by the function `garchFit()`.
- `predict` - is a generic function to forecast from an estimated model.

In this example we estimate the parameters for a GARCH(1,1) model with normal innovations. The process can be decomposed in five steps :

- Parameter initialization
- Conditional distribution
- Log-likelihood function
- Parameter estimation
- Summary report

# Parameter initialization

## Introduction

Mean and variance  
equation

## fSeries : a R/Rmetrics implementa- tion

An unique GARCH  
modelling approach

### How to fit GARCH(1,1) model

we initialize the set of model parameters  $\theta$ , params, and the corresponding upper and lower bounds.

```
garchInit = function(series) {  
  Mean = mean(series); Var = var(series); S = 1e-6  
  params = c(mu = Mean, omega = 0.1*Var, alpha = 0.1, beta = 0.8)  
  lowerBounds = c(mu = -10*abs(Mean), omega = S^2, alpha = S, beta = S)  
  upperBounds = c(mu = 10*abs(Mean), omega = 100*Var, alpha = 1-S, beta = 1-S)  
  cbind(params=params, lowerBounds=lowerBounds, upperBounds=upperBounds)  
}
```

# Conditional distribution

GARCH(1,1) model  
and the DEMGBP  
benchmark

MA(1)-APARCH(1,1)  
model and the  
SP500 benchmark

For the conditional distribution we use the Normal  
distribution `dnorm()`.

```
garchDist = function(z, hh) {dnorm(x = z/hh)/hh }
```

## Log-likelihood function

The quasi-maximum likelihood technique applied to a GARCH(1,1) process leads then to the following optimisation problem

$$\min \mathcal{L}_N(\theta) = \frac{1}{2} \sum_t \left[ \ln 2\pi + \ln \sigma_t^2 + \frac{\varepsilon_t^2}{\sigma_t^2} \right]$$

*subject to*

$$x_t - \mu - \varepsilon_t = 0$$

$$\sigma_t^2 - \omega - \alpha \varepsilon_{t-1}^2 - \beta \sigma_{t-1}^2 = 0$$

$$-\omega \leq 0$$

$$-\alpha \leq 0$$

$$-\beta \leq 0$$

$$\alpha + \beta - 1 \leq 0$$

In our example we use a fast and efficient filter  
representation for the variance equation.

```
garchLLH = function(parm, series) {  
  mu = parm[1]; omega = parm[2]; alpha = parm[3]; beta = parm[4]  
  z = (series-mu)  
  Mean = mean(z^2)  
  # Use Filter Representation:  
  e = omega + alpha * c(Mean, z[-length(series)]^2)  
  h = filter(e, beta, "r", init = Mean)  
  hh = sqrt(abs(h))  
  llh = -sum(log(garchDist(z, hh)))  
  llh  
}
```

We use the constrained solver `nlmminb()` which is available in R and SPlus.

```
garch11Fit= function(series, params, lowerBounds, upperBounds) {  
  fit = nlmminb(start = params, objective = garchLLH,  
                lower = lowerBounds, upper = upperBounds,  
                control = list(trace=3),series=series)  
  fit  
}
```

Gabriele Fiorentini, Giorgio Calzolari, and Lorenzo Panattoni. 1996.

- Fiorentini et al. [1996] (FCP) took the daily percentage nominal returns for the German mark/British sterling exchange rate, henceforth (DEMGBP), as published by Bollerslev and Ghysels [1996].
- FCP calculated the set of parameters for the GARCH(1,1) process with the help of analytical derivatives and Hessian of the conditional log-likelihood.
- The FCP implementation constitutes today a well accepted benchmark.

# DEMGBP benchmark

The series contains a total of 1975 daily observations sampled during the period from January 2, 1984, to December 31, 1991.
